Acknowledgements

This work was supported through contracts with the New York District of the U.S. Army Corps of Engineers. We would like to thank R. Muller, M. Anders, C. Arnold, L. Benson, C. Jones, and M. Zimmerman-Berger for carrying out the field and laboratory analyses. In addition, we are grateful to B. Malione, M. Beristain, M. Dornblaser, R. Eppi, J. Hennessy, M.A. O'Hare, E. Osking, and A. Subramanian for their help in the field and to C. Decker, M. Jacobson, W.S. Kim, and K. Swider for their assistance in the lab.

Introduction

In Bokuniewicz and Cerrato (1985), an empirical procedure was developed to identify potential sites in the Lower Bay for a large containment island. This procedure was used to evaluate areas by incorporating benthos and finfish data under a variety of different relative weighting schemes. As a result of this analysis, three areas of the Lower Bay persistently emerged as likely sites for a containment facility (Figure 1A).

In carrying out this empirical analysis, we felt that further progress toward identifying a site for a containment island was limited in part by inadequacies in the benthic data base available at that time. To eliminate these inadequacies, we have carried out a regional benthic survey of the Lower Bay and site specific sampling within each of the three potential containment island areas during 1986-87. The goals of this study were to 1) test the siting predictions made in Bokuniewicz and Cerrato (1985) and 2) provide detailed, seasonal information on the current state of the benthic resources within the Lower Bay and at each potential containment island site.

To date, the results of the 1986-87 survey have been incorporated into the site selection procedure, and the conclusions reached from that analysis are given in Cerrato et al. (1988) (Figure 1B). The purpose of this current report will be to address the second goal of the study. This report will describe in quantitative detail the distribution and abundance of the benthos, the nature and characteristics of the surficial sediments, and the distribution of other relevant environmental variables such as depth, temperature, and salinity in the Lower Bay.

Background

1. Regional Coverage

The critical component in the empirical selection procedure developed by Bokuniewicz and Cerrato (1985) was the use of regional or "mappable" sets of biological data. It was assumed that valid comparisons of the biological resources in the Lower Bay could only be carried out using data sets which covered a large portion of the Bay and which were adequate enough in their coverage to see gradients in the data.

The Lower Bay has been perhaps the most extensively studied area of the Hudson River estuary. Previous studies reporting on the benthos in this region include Walford (1971), McGrath (1974), Dean (1975), Woodward and Clyde (1975a,b), Gandarillas and Brinkhuis (1981), Cerrato and Scheier (1984), and Stainken, et al. (1984). Most of these studies involved limited spatial sampling. Walford (1971), for example, sampled at only eight stations on the West Bank. Woodward and Clyde (1975a,b) collected benthic samples at eleven stations on the East Bank south of Coney Island. Gandarillas and Brinkhuis (1981) carried out an intensive seasonal survey at 74 stations, but it was limited to two proposed mining sites on the East Bank and near Old Orchard Shoal and a control area near Romer Shoal. The study by Cerrato and Scheier (1984) was restricted to examining the benthic fauna at two sand borrow areas and one control site on the West Bank.

In only three of the previous benthic surveys (Dean, 1975; McGrath, 1974; Stainken, et al., 1984) were attempts made to cover substantial portions of the Lower Bay. Dean (1975) collected benthic samples during each summer from 1957 to 1960. Samples were collected using a 0.1 m^2 Peterson or van Veen grab and sieved through a 1.5 mm mesh screen. A total of 73 stations were sampled during this study. Most of these stations were concentrated in Raritan Bay and only 25% of the locations were east of a transect running from Great Kills to Point Comfort. Significant portions of the Lower Bay such as Flynn's Knoll, Romer Shoal, and the East Bank were not sampled by Dean, and only one station was established in Sandy Hook Bay.

In McGrath's (1974) survey, benthic samples were taken with a 0.1 m^2 Smith-McIntyre grab. All samples were sieved on a 1.0 mm mesh screen. McGrath collected samples at 65 stations during January-February 1973. Additionally, seasonal samples were also collected at stations in Sandy Hook Bay. Station locations for the January-February 1973 survey were for the most part uniformly distributed throughout the Lower Bay and were spaced approximately 1 nm apart. Despite the extensive nature of this survey, several important areas (i.e., the East Bank and Gravesend Bay) were not included, while other areas (e.g., Flynn's Knoll and Romer Shoal) received minimal coverage. In terms of spatial coverage, McGrath's survey was the most complete of all prior benthic studies in the Lower Bay. For this reason, the results of this survey were included in the original site selection analysis conducted by Bokuniewicz and Cerrato (1985).

Stainken, et al. (1984) reoccupied McGrath's stations during a benthic survey conducted from June 1979 to May 1980. Samples were collected with a 0.1 m^2 Smith-McIntyre grab and sieved through a 10 mm mesh screen. Because of the large sieve size, this study does not provide results which can be used to analyze community structure.

2. Temporal Changes

Aside from inadequacies in spatial coverage noted above, a second major weakness in the data base for the Lower Bay was that the existing regional surveys could not be used to adequately assess temporal changes in the benthic fauna. Attempts to evaluate long term changes have been made by Berg and Levinton (1984) and Diaz and Boesch (1984). Both of these studies concentrated on comparing the regional surveys of Dean (1975) and McGrath (1974). The two surveys, however, differ notably in terms of sampling location, season of collection (summer vs. winter), and the screen sizes used to sieve the samples (1.5 mm vs. 1.0 mm). Both Diaz and Boesch (1984) and Berg and Levinton (1984) emphasized that differences in sampling design and methods limited the conclusions that could be reached from a comparison of the two surveys. Diaz and Boesch, for example, noted that only "substantial changes in community structure and near eliminations of populations of common species" could be detected because of these differences. Additionally, the more recent of these two surveys (i.e., McGrath, 1974) was carried out well over a decade ago, and substantial changes in the benthos may have taken place over time.

On a shorter time scale, little is known of the seasonal variations in benthic distributions on a bay-wide basis (Berg and Levinton, 1984). The two regional surveys by Dean and McGrath were static surveys (Berg and Levinton, 1984); each were done in only one season. Seasonal variations are known to be quite substantial in some areas of the Lower Bay. Cerrato and Scheier (1984), for example, found highly variable seasonal patterns in the benthic fauna within borrow pits on the West Bank. In one pit, benthic abundances changed by over two orders of magnitude in a span of only three months (Cerrato and Scheier, 1984). During this same period of time, a three-fold change in the average number of species per sample was observed (Cerrato and Scheier, 1984). While borrow pits are not representative of typical habitats within the Lower Bay, these results show the potential for large scale seasonal changes and illustrate the shortcomings in comparing surveys which differ in season of collection. They also point out the need to collect and assess seasonal data as part of the site selection process.

3. Availability of Site Specific Data

Specific information on the benthic fauna at the three potential containment island sites identified by Bokuniewicz and Cerrato (1985) was for the most part limited. At the Raritan Bay site, only two stations sampled by Dean (1975) and one taken by McGrath (1974) were located within the designated area.

Neither Dean nor McGrath collected samples at the East Bank area. The only recorded sampling at this location was reported in Brinkhuis (1980). During February and March 1978, Brinkhuis collected benthic samples at nine stations located within the southern half of the East Bank site. Samples were collected using a 0.04 m^2 Shipek grab and sieved through a 1 mm mesh screen.

For the West Bank area, McGrath (1974) collected benthic samples at only one location within and at two adjacent stations. None of Dean's sampling stations were in the immediate vicinity of this site. However, the northernmost 250 acres of the West Bank site, representing about 15% of the designated area, along with immediately adjacent locations, has been extensively surveyed by Gandarillas and Brinkhuis (1981) and later by Cerrato and Scheier (1984). Gandarillas and Brinkhuis collected benthic samples on a seasonal basis at 25 stations on Old Orchard Shoal between May 1979 and May 1980. Cerrato and Scheier obtained seasonal benthic samples in this same area between October 1980 and July 1983. Both studies used comparable methods; samples were collected with a 0.04 m^2 Shipek grab and washed through a 1 mm mesh screen. Combining the results of the two studies, Cerrato and Scheier assembled a contiguous, four year long, seasonal record of the benthic fauna in this area.

The overall usefulness of the existing site specific data was limited by a number of factors. With the exception of the northernmost portion of the West Bank site, the existing information was fairly old, spatial coverage within each site was not extensive, and seasonal variations in the benthic fauna had not been documented. Furthermore, the data in the surveys were not collected synoptically and each study utilized somewhat different sampling

methodologies. As a result, an assessment of the benthic fauna within each potential containment island site, among sites, or even between sites and the Lower Bay as a whole could not be made with confidence.

Methods

1. Sampling Procedures

Sampling methods in the 1986-87 benthic survey were designed to eliminate existing inadequacies in the benthic data base. The survey consisted of both a regional study of the Lower Bay and site specific sampling within the three potential containment island areas. Benthic samples were collected during four seasonal cruises (spring, summer, fall, and winter) aboard the R/V ONRUST. A total of 114 stations were sampled on each of the seasonal cruises. The exact sampling dates were 28 April-2 May, 21-25 July, 6-10 October 1986, and 12-16 January 1987.

The regional survey consisted of seasonal sampling at 84 stations (Figure 2). This part of the study was designed to provide representation from all of the major environments in the Lower Bay and to yield mappable data sets which could be incorporated into the site selection procedure. The sampling scheme (and station numbering scheme) was based on McGrath's (1974) survey with several notable exceptions. Several stations (designated by McGrath as stations 20, 22, 23, 29, 44, and 45) falling within or adjacent to the potential containment island sites on the West Bank and Raritan Bay were deleted since these areas received extensive coverage in the site specific part of the study. Three stations in western Raritan Bay (designated by McGrath as stations 33, 61, and 64) were also eliminated to maintain spatial coverage at a level comparable in density to the rest of the Lower Bay. Seven locations, identified as stations 38, 39, 53, 54, 55, 59, 60, and 84, apparently not sampled by McGrath (1974) were included in the 1986-87 survey. Seventeen additional sampling locations, identified as stations 89 to 105 in Figure 2, were included to provide coverage within Gravesend Bay, Flynn's Knoll, Romer Shoal, and the East Bank. Minor adjustments in some of McGrath's original station locations were made to insure that the sampling reflected the distribution of major sediment types as mapped by Coch (1986).

For the three potential containment island sites, seasonal benthic samples were collected at 10 stations per site. This part of the study was designed to provide detailed site specific data that would allow comparisons to be made of the benthos within a site, among sites, and between sites and the rest of the Lower Bay. According to Coch (1986), all three sites consisted of two or more distinct sediment types. Therefore, sampling was stratified to reflect both bathymetry and sediment composition.

Sampling stations were located using a Texas Instruments 9900 II Loran C. This instrument provides a direct readout of latitude and longitude, and the unit was calibrated using a local reference point of known location during each cruise. Radar fixes and local landmarks were used to double check station locations. The latitude and longitude of each station is given in Table 1.

Benthic samples were taken using a 0.1 square meter Smith-McIntyre grab. Two replicate grabs per station were collected on each cruise for biological study. During the spring and winter cruises, a portion of a third grab was saved untreated for sediment analysis. A Martek MK VI multiparameter analyzer was used to obtain measurements of depth, bottom temperature, and conductivity at each station. Salinity was later calculated from recorded parameters based on the Practical Salinity Scale of 1978.

Grab samples for biological study were wet-sieved onboard immediately after collection. Sieves were constructed of 1 mm diameter Nitex screening. After washing, all material retained on the screen (e.g., animals, detritus, sand, gravel, shell fragments, etc.) was transferred to labeled sample jars. These samples were preserved in 10% buffered formalin and stained with rose bengal.

2. Laboratory Procedures

With the exception of the summer cruise, biological samples were rewashed in the laboratory using a 1 mm screen and transferred to 70% ethyl alcohol. To obtain compatibility with Dean's (1975) study, samples collected in summer were partitioned into two subsamples by sieving through both a 1.5 and 1.0 mm mesh screen. Samples were then analyzed using a two stage process. In the first stage, animals were picked from the sediments, detritus, etc. under an illuminated magnifier and sorted to phylum level. In the second stage, individual organisms were identified to species level whenever possible, and the total for each taxa enumerated. All data were initially entered on log sheets and later transferred to a computer.

For the sediment analysis, each sample was homogenized, and a subsample of approximately 10 g was taken. Particle size distributions were determined by wet sieving and pipette analysis (Folk, 1964). Subsamples were dispersed with a 1% Calgon solution (sodium hexametaphosphate) and mechanically agitated for one hour to disaggregate the particles. The subsample was wet sieved into a 1000 ml graduated cylinder using a combination of a 2 mm mesh sieve and a 63 micron mesh sieve to separate the gravel, sand, and mud fractions. The mud fraction in the graduated cylinder was separated into silt and clay by taking two pipette withdrawals. Sediment fractions separated during this process were dried in an oven at 80-90 degrees C, cooled to room temperature, and weighed. Weights of the silt and clay fractions were corrected for the amount of Calgon added. Mass percentages of the four particle size categories were calculated as percentages of the total subsample weight. No correction was made for salt content in the pipetted samples because the error introduced was considered insignificant. Organic content of the samples was measured as the weight loss after combustion at 450 degrees C for at least four hours. All data were initially entered on log sheets and later transferred to a computer.

3. Data Analysis

A number of derived parameters or indices (abundance, species richness, Shannon-Wiener diversity, and equitability) were computed from the biological data. Nonenumerable species (e.g., colonial organisms such as hydrozoans)

were tabulated in calculating species richness but were excluded from all other computations. The occurrence of these taxa is reported on the data sheets at the end of this report.

Abundances are reported as the number of individuals per square meter. These estimates were obtained by dividing the sample results by the sampling unit area (0.1 m^2). Species richness is presented as the number of species per 0.1 m^2 . Because the relationship between the number of species and sampling unit area is nonlinear, normalization to a standard unit such as number per square meter is not possible for this parameter. Station maps in the results section represent per sample values of abundance and species richness averaged for each station.

Two indices of diversity were used to analyze the biological data. The first index is the Shannon-Wiener information function:

$$H'(s) = -\sum_{i=1}^s p_i \log_2 p_i$$

where s is the total number of species and p_i is the proportion of individuals in the sample belonging to the i th species ($i = 1, 2, 3, \dots, s$). Shannon-Wiener diversity measures both species richness (i.e., the number of species in a sample) and the distribution of individuals among species (termed evenness or equitability). This index has a minimum value of 0. High values of H' represent diverse assemblages. Diversity was computed for each sample in the study. Station maps in the results section represent average per sample values for that station.

The second index of diversity is the equitability or evenness function:

$$V' = H'(s)/H'_{\max}$$

where $H'_{\max} = \log_2 s$. This index has a range from 0 to 1. The higher the value of V' , the more evenly individuals in a sample are distributed among the s species. Equitability was computed for each sample, and station maps in the results section represent average per sample values for that station.

Station maps in the results section were created using a software package called SURFER (Golden Software, Inc.). SURFER is a flexible computer program which can present distributional data in a variety of two and three dimensional formats. Contour lines were produced within SURFER by first generating a regularly spaced grid of interpolated values from the irregularly spaced distributional data. Each element in the regularly spaced grid was computed as a weighted mean of the three nearest data points. The weighting factor was based on the inverse squared distance between the grid element and the location of each data point. With this algorithm, data points nearest the location of the grid element carry greater weight than points further away. The resulting grid was next smoothed using a cubic spline interpolation algorithm. This procedure serves to reduce the angular appearance of the

contour lines. In the last step, contour line were drawn based on the gridded values, and land areas and data values were overlaid to produce the final plot.

The locations of the three original potential containment island sites, channels, and the 18 foot depth contour are plotted in Figure 3. This figure, if copied onto a transparency, may be overlaid on the maps in the results section to examine the data in relation to these features.

Results

1. Hydrographic Parameters

Data on depth, temperature, and salinity were collected on every seasonal cruise at each station. A tabular listing of these parameters is given in Appendix A.

a. Depth

Station depths for each seasonal cruise are presented in Figures 4-7. Depths ranged from 2 to 21 meters. The average depth of the stations in this study was 7 meters.

b. Temperature

During the spring cruise, bottom temperatures in the study area ranged from 8.9° to 12.9°C (Figure 8). The average temperature for all stations was 10.7°C . Lowest temperatures were found in the eastern section of the Lower Bay, including an area associated with Chapel Hill Channel and a second area within Sandy Hook Bay. Highest temperatures were in Raritan Bay, especially in the shallow areas bordering New Jersey.

For the summer cruise, bottom temperatures ranged from 19.7° to 24.4°C (Figure 9). This is the largest temperature range observed during the study. The average temperature for all stations was 22.5°C . A fairly clear east-west gradient in temperature is evident, with the lowest temperatures found along the Sandy Hook - Rockaway Point transect and with temperatures gradually increasing to the west.

In the fall, bottom temperatures ranged from 14.6° to 18.2° and averaged 16.8° for the entire study area (Figure 10). Temperatures were for the most part fairly uniform throughout the Lower Bay, with the exception of a slightly colder area associated with Chapel Hill Channel. The highest temperatures were again observed in Raritan Bay.

During the winter cruise, the average bottom temperature in the Bay was 4.5°C , and temperatures at individual stations ranged from 3° to 6.3°C (Figure 11). Highest temperatures were found along the Sandy Hook - Rockaway Point transect. An east-west gradient of decreasing bottom water temperatures is evident at this time, and lowest temperatures were observed in Raritan Bay.

c. Salinity

For the spring cruise, bottom salinities ranged from 18.4 to 30.9 ppt (Figure 12). This was the largest range found during the study. The average salinity for all stations was 24.6 ppt. Salinities were highest off Rockaway Point and declined to the northwest in the direction of the Narrows and also westward towards Raritan Bay. Lowest salinities were found in Raritan Bay in the shallow areas along the New Jersey shoreline.

Bottom salinities in the summer ranged from 24.4 to 30.9 ppt (Figure 13) and averaged 27.1 ppt for the entire study area. Salinities were for the most part fairly uniform throughout the Bay. Highest values occurred off Rockaway Point and in an area associated with Chapel Hill Channel. Lowest salinities were observed in Raritan Bay along the shore of New Jersey.

During the fall cruise, the range in bottom salinity was from 18.2 to 29.3 ppt (Figure 14). The average salinity for all stations was 25.8 ppt. Like the summer cruise, salinities were again fairly uniform throughout the Bay. There was, however, a slight north-south gradient in salinity at this time. Lowest salinities were found along the entire New Jersey shoreline, and values gradually increased to the north. A second area of low salinity was also found in the northern area of the Lower Bay along the shoreline of Staten Island.

In the winter, salinity values ranged from 18.8 to 30.9 ppt (Figure 15). The average salinity for all stations was 24.7 ppt. Highest values occurred off Rockaway Point, and like the spring cruise, salinity declined to the northwest in the direction of the Narrows and also westward towards Raritan Bay. Lowest salinities were observed along the New Jersey shoreline within Raritan Bay. Low salinities were also found in Sandy Hook and Gravesend Bay.

2. Sediment Characteristics

Sediment samples were collected at each station during the spring and winter cruises. Grain-size analysis was carried out on both sets of samples. The organic content of the sediments was determined only for the set taken in the spring. Results are tabulated in Appendix B.

The general distribution of sediments within the Lower Bay is most clearly seen by examining plots of percent silt-clay given in Figures 16-17. Muddy sediments are found in a band running in a southeast to northwest direction from Sandy Hook Bay to Staten Island. Fine-grained sediments are also characteristic of the inner portion of Raritan Bay. In the north, muddy sediments are for the most part associated with borrow pits on the East and West Bank.

a. Percent Gravel

Gravel content in the surficial sediments ranged from 0 to 52.2% based on results from the spring cruise and from 0 to 74.8% as determined from the winter cruise samples (Figures 18 and 19). Despite the wide range of values, gravel content was generally low at most stations within the study area.

Exceptions to this include patches of high percent gravel off Rockaway Point, off the western end of Coney Island, and to the southwest of Great Kills Harbor. Average percent gravel for all stations was 4.5% in the spring and 4.8% for the winter cruise.

b. Percent Sand

Sand content in the surficial sediments ranged from 1.9 to 99.3% in the spring and from 0.4 to 100.0% during the winter cruise (Figures 20 and 21). Areas with sand values exceeding 90% include Old Orchard Shoal, Flynn's Knoll, Romer Shoal, the East Bank, and an area along the New Jersey Shoreline between Raritan Bay and Sandy Hook Bay. The average for all stations was 62.4% and 60.3% for the spring and winter cruises, respectively.

c. Percent Silt

During the spring cruise, percent silt in the surficial sediments ranged from 0 to 60.8% (Figure 22) and averaged 17.8% for the entire study area. From the results of the winter cruise, silt content ranged from 0 to 99.5% (Figure 23), and the overall average for the study area was 18.6%. Areas of high silt include the borrow pits on the East and West Bank, the band of muddy sediments running from Sandy Hook Bay to Staten Island, and inner Raritan Bay.

d. Percent Clay

High clay content sediments were distributed in a manner similar to that found for percent silt. Values of high percent clay were found within the borrow pits on the East and West Bank, the muddy region from Sandy Hook Bay to Staten Island, and within Raritan Bay. Clay contents ranged from 0 to 49.7% in the spring and 0 to 62.2% during the winter cruises (Figures 24 and 25). The average value for all stations was 15.4% and 16.3% for the spring and winter cruises, respectively.

e. Organic Content

High organic content sediments correspond fairly well to the muddy regions within the Lower Bay (Figure 26). The areas of high organic content include the borrow pits on the East and West Bank, inner Raritan Bay, and the band of muddy sediments running from Sandy Hook Bay to Staten Island. Organic content in the surficial sediments collected during the spring cruise ranged from 0.1% to 15.5%. The average for the entire study area was 4.9%.

3. Biological Characteristics

Two replicate grabs at each of the sampling stations were collected and analyzed for all four seasonal cruises. A total of 521072 animals representing 213 taxa were taken. A composite species list is given in Table 2. Of the 213 taxa, 69 (32%) were Polychaetes, 39 (18%) were Molluscs, and 65 (31%) were Crustaceans. The remaining taxa were distributed among ten other groups: Porifera, Cnidaria, Platyhelminthes, Rhynchocoela, Aschelminthes, Ectoprocta, Phoronida, Oligochaeta, Echinodermata, and Chordata.

Station and study area summaries are reported in detail in this section. Data for each grab sample are tabulated in Appendix C. Abundance, species richness, diversity, and equitability results for each sample may be found in Appendix D. One other data set is also included in the appendices. In Appendix E, the results for the summer cruise based on a 1.5 mm mesh sieve are presented. This data set, using the larger sieve size, is directly comparable to the results of Dean's (1975) study.

a. Species Composition

Numerically dominate fauna were identified by pooling the data from all samples and ranking species by abundance. A listing of the most abundant species in the study area is given in Table 3. The 78 taxa appearing in this table represent 99.75% of all individuals collected. The tubicolous amphipod, Ampelisca abdita, was by far the most abundant species found in the samples. This species alone accounted for 55.8% of the total fauna. The blue mussel, Mytilus edulis, was also numerically dominant, representing 18.6% of all individuals taken. Other dominants included the polychaetes Asabellides oculata (2.8%) and Heteromastus filiformis (1.7%), the gastropod Crepidula fornicate (1.1%), the bivalve Mya arenaria (1.3%), and the amphipods Corophium tuberculatum (4.5%) and Elasmopus levis (1.0%). All other species individually represented less than 1% of the total fauna. The distribution of these species, along with several bivalves of commercial importance, will be presented in the remainder of this section.

The tubicolous amphipod Ampelisca abdita (Figures 27-30) was found in high numbers throughout the year within the band of muddy sediments which runs in a southeast to northwest direction from Sandy Hook Bay to Staten Island. It was also collected in moderate numbers in the northern portion of the study area, especially along Staten Island and within Gravesend Bay. It was conspicuously low in abundance or entirely absent in the sandy areas of Old Orchard Shoal, Flynn's Knoll, Romer Shoal, and the East Bank. During the spring cruise, A. abdita was collected in low numbers within the inner portion of Raritan Bay. However, it was fairly common in this area during the remainder of the year.

The blue mussel, Mytilus edulis, was the second most abundant species taken in this study (Figures 31-34). However, unlike A. abdita, it was found mostly in the northern portion of the study area. Mussels were most abundant in an area west of Rockaway Point and in a second area both west and south of the tip of Coney Island. Most of the individuals collected in the spring were small juveniles, and abundances steadily declined throughout the year in both of these areas. Mussels were also consistently taken in moderate numbers within Sandy Hook Bay during all cruises.

The distribution of Corophium tuberculatum during the four seasonal cruises is given in Figures 35-38. Like A. abdita, this species is a tubicolous amphipod which was most abundant in the band of muddy sediments running from Sandy Hook Bay to Staten Island. Abundances in this area peaked in the summer, and this species appeared to decline in numbers throughout the rest of the year. By the winter cruise, it was rare or absent from most stations within Sandy Hook Bay. C. tuberculatum was conspicuously absent in

much of the northern half of the study area with the exception of nearshore areas along Staten Island and within Gravesend Bay. It was also rarely taken within the inner portion of Raritan Bay.

Asabellides oculata is a tubiculous, surface deposit feeding polychaete (Figures 39-42). Peak abundances of this species were found during the spring cruise, and high numbers were probably the result of recruitment during the previous fall. During the spring, it was abundant primarily in the eastern half of the Bay, especially within the channels, several borrow pits, and other deeper areas. By summer, this species declined substantially at most stations in the eastern portion of the Bay. It did, however, appear to recruit in the western half of the Bay. In fall and winter, A. oculata declined and was found in low numbers only in isolated patches.

The distribution of Heteromastus filiformis is shown in Figures 43-46. This species is a tubiculous, infaunal, deposit feeding polychaete. H. filiformis tended to be rare or absent from the entrance of the Lower Bay (i.e., just west of the Sandy Hook to Rockaway Point transect) and within the inner portion of Raritan Bay. The general distribution of this species did not change substantially over time, and it was a consistent member of the fauna along the shorelines of Staten Island and New Jersey. It was also abundant within the muddy band of sediments running from Sandy Hook Bay to Staten Island.

The distribution of the soft shell clam Mya arenaria, is presented in Figures 47-50. Soft shell clams were most abundant in Raritan Bay, although they were not consistently taken within the inner reaches. Peak abundances occurred in the summer, when Mya was collected at almost all stations south of a line running from the tip of Sandy Hook to Great Kills Harbor. With the exception of the dense population within Raritan Bay, abundances tended to remain low or decline in the fall and winter.

The distribution of the slipper shell, Crepidula fornicate, during the four seasonal cruises is presented in Figures 51-54. During the spring and summer, this species was taken along the central portion of Staten Island southward to New Jersey. Peak abundances occurred in the fall. By this time, recruitment appears to have taken place and its range extended into Raritan and Sandy Hook Bays. Moderately high numbers were also found in the winter cruise.

The distribution of the amphipod Elasmopus levis is given in Figures 55-58. During the spring and summer, it was found in moderate numbers along Staten Island, in Gravesend Bay, to the west of Rockaway Point, and to the northwest of the tip of Sandy Hook. Abundances peaked in the fall, and this species was taken throughout the Bay with the exception of portions of the East Bank and Old Orchard Shoal. By winter, E. levis declined in abundance, and it was absent from a broad area north of Sandy Hook.

In addition to Mytilus edulis and Mya arenaria, three bivalve species of commercial value also occurred within the Lower Bay. The hard clam Mercenaria mercenaria was patchily distributed throughout much of the Bay with the exception of the southern half of Raritan Bay and the East Bank (Figures

59-62). The surf clam Spisula solidissima was consistently taken west of the Sandy Hook to Rockaway Point transect (Figures 63-66). During the summer and fall cruises, it was also found in sandy areas along the Staten Island and New Jersey shorelines. Oysters, Crassostrea virginica, were rare and were only collected in isolated patches during the spring and summer cruises (Figures 67-70).

b. Abundance

The spatial pattern in abundance for the spring cruise is given in Figure 71. Average station abundances ranged from 5 to 71605 animals per square meter. The average abundance for the entire study area was 7264 individuals per m^2 . Abundances were high in the band of muddy sediments running from Sandy Hook Bay to Staten Island. Values were also high west of Rockaway Point and in the northern portion of the study area surrounding the tip of Coney Island. Low abundances were found in Raritan Bay, along the New Jersey shoreline, and in the sandy areas of Old Orchard Shoal, Flynn's Knoll, the southern half of Romer Shoal, and the East Bank.

During the summer cruise, abundances ranged from 25 to 65995 individuals per m^2 (Figure 72). The overall average for the study area was 5502 animals per square meter. Abundances were generally high throughout the southern half of the study area. Exceptions to this include the inner portion of Raritan Bay and an area along the central New Jersey shoreline. Within the northern portion of the study area, high abundances were found in areas to the west of Rockaway Point, to the south and west of the tip of Coney Island, and along northern Staten Island.

In the fall, the overall average abundance for the study area was 5778 individuals per square meter, and station values ranged from 15 to 34120 individuals per m^2 (Figure 73). High abundances were again observed at most stations in the southern half of the Bay. The northern portion of the study area was generally lower in abundance, with the exception of areas to the west of Rockaway Point, to the west and south of the tip of Coney Island, and along the Staten Island shoreline.

By winter, the north-south pattern in abundance was still evident, although notable declines at some of the high abundance stations were observed (Figure 74). The average abundance for all stations also declined to 4309 animals per square meter. Station averages ranged from 5 to 50545 individuals per m^2 .

c. Species Richness

The spatial pattern of species richness, expressed as the average number of species per $0.1\ m^2$, was somewhat more complicated than that observed for abundance. High values of species richness appeared to be associated with the shallow nearshore regions (Figures 75-78). There were, however, several notable exceptions to this pattern. Low values of species richness tended to occur consistently in the shallow areas of Raritan Bay, Flynn's Knoll, Romer

Shoal, and the East Bank. High values in deep water included Gravesend Bay, an area to the west and south of Coney Island, and a region in the central portion of the Bay.

During the spring cruise, values of species richness ranged 0.5 to 37 species per 0.1 m^2 . The average for all stations was 14.2 species per 0.1 m^2 . High values were found within Gravesend Bay, south and west of the tip of Coney Island, along the central portion of Staten Island, and within Sandy Hook Bay.

In summer, values for this parameter ranged from 2 to 39.5 species per 0.1 m^2 . High values were found primarily in nearshore areas along New Jersey, Staten Island, Gravesend Bay, and south of Coney Island. The average for the entire study area was 16.0 species per 0.1 m^2 .

The general pattern of high values in nearshore areas was again apparent during the fall cruise. The average for the Bay as a whole was 15.6 species per 0.1 m^2 . Values for individual stations ranged from 1.5 to 36 species per 0.1 m^2 .

In winter, values of species richness declined slightly, and the pattern of high numbers of species inshore was not as well defined as it had been during the two previous seasonal cruises. Values for this parameter ranged from 0.5 to 31.5 species per 0.1 m^2 . The average for all stations within the study area was 13.9 species per 0.1 m^2 .

d. Diversity

The distribution of Shannon-Wiener diversity values during the spring cruise is presented in Figure 79. Values ranged from 0 to 3.97 and averaged 1.70 for all stations within the study area. In the south, diversity was high in the shoreline areas along New Jersey and low in the band of muddy sediments running from Sandy Hook Bay northwest to Staten Island. In the northern portion of the study area, diversity was high on Old Orchard Shoal, Flynn's Knoll, Gravesend Bay, and to the southwest of the tip of Coney Island. Low values were found on Romer Shoal, portions of the East Bank, and within the borrow pits on the West Bank.

During the summer cruise, the same general pattern was observed (Figure 80). In the southern half of the Bay, diversity was low in the band of muddy sediments running from Sandy Hook Bay to Staten Island. High values were observed along the shorelines of New Jersey and the southern tip of Staten Island. In the northern half of the study area, high diversities were found on Old Orchard Shoal, Gravesend Bay, west and south of the tip of Coney Island, and parts of Flynn's Knoll and Romer Shoal. Diversity was low on the East Bank and within several borrow pits on the West Bank. Diversity values at individual stations ranged from 0.28 to 3.87 and averaged 1.94 for the bay as a whole.

The distribution of diversity values for the fall cruise is given in Figure 81. Diversity values tended to be low in general throughout the southern half of the study area, with exception of several patches within

Raritan Bay and along the New Jersey shoreline. Diversities were relatively higher in the northern portion of the Bay, except for an area which included Romer Shoal and part of the West Bank. Average station values ranged from 0.29 to 3.90. The average for all stations was 1.76.

For the winter cruise, a distinct north-south pattern in diversity was evident (Figure 82). Low diversities were generally found in the southern portion of the Bay, while high values were observed in the north. Values ranged from 0 to 3.91. The average for all stations during this season was 1.95.

e. Equitability

Spatial patterns in equitability are presented in Figures 83-86. In general, trends in equitability were similar to that of diversity, with a fairly complex pattern gradually simplifying to a distinct north-south gradient during the course of the survey. In the spring, equitability values ranged from 0 to 0.96 and averaged 0.50 for the entire study area. Within the southern half of the Bay, equitability values were high along the New Jersey shoreline and low within the band of muddy sediments running from Sandy Hook Bay to Staten Island. In the north, equitability was high on Old Orchard Shoal, Flynn's Knoll, and on portions of Romer Shoal and the East Bank. Low values for this parameter were observed in Gravesend Bay, on the West Bank, and at several stations south of Coney Island.

By the summer cruise, the area of high equitability within the southern portion of the study area appeared to have broken up into several patches. Conversely, fewer stations within the northern portion of the study area had low values for this parameter. Equitability values ranged from 0.07 to 0.92 at this time. Average equitability for all stations in the study was 0.54.

During the fall cruise, equitability values ranged from 0.08 to 0.90 and averaged 0.49 for the entire study area. Equitability values were generally low within the southern half of the Bay. In the north, equitability values were high at most stations.

In winter, the north-south trend in equitability was still clearly evident. Values at this time ranged from 0 to 1. The average for all stations was 0.57.

Discussion

The most striking feature of this study concerns the state of the benthic fauna in the Lower Bay. Abundance averaged 5714 individuals per m^2 during the year long period examined. Table 4 compares this result to other nearshore benthic habitats. Average abundance in the present study was higher than that found in most local areas including Newark Bay, Flushing Bay, Bowery Bay, the south shore of Long Island, and the New York Bight. In addition, average abundance was high in relation to prior studies of the Lower Bay, with the exception of Woodward and Clyde (1975a,b). Even excluding the two

dominant species, Ampelisca abdita and Mytilis edulis, the abundance of the remaining fauna averaged 1466 individuals per m^2 . This value is still comparable to many of the studies listed in this table.

Steimle and Caracciolo-Ward (in review) have completed a reanalysis of samples archived from McGrath's (1974) survey. Their work indicates that 156 species were taken from the 65 stations in the study. In addition, they estimated an average abundance of 660 animals per square meter and an average species richness value of 6 per 0.1 m^2 grab. From the results of the present study, 213 taxa were taken. Abundance averaged 5714 individuals per m^2 , and the average number of species per 0.1 m^2 grab was 14.9. This abundance estimate is over eight times higher than the estimate based on McGrath's sample set. The average number of species per grab is more than a factor of two higher. Given these substantial differences, it is clear that considerable changes have taken place in the Lower Bay since 1973.

Summary

This report presents the results of a bay-wide, seasonal benthic study of the Lower Bay of New York Harbor. A total of 912 biological and 228 sediment samples were collected along with information on depth, temperature, and salinity during the period from April 1986 to January 1987. Biological data are presented in terms of species composition, abundance, species richness, Shannon-Wiener diversity, and equitability. The principal results and conclusions of this study are:

1) Spatial gradients in temperature and salinity were apparent during several of the seasonal cruises. In particular, bottom temperatures showed a distinct east-west trend during the spring, summer, and winter cruises. Bottom salinities were highest off Rockaway Point and declined in the direction of the Narrows and Raritan Bay. Salinity gradients were most apparent during the spring and winter cruises.

2) As expected, surficial sediments were quite variable, ranging from 100% sand and gravel to 100% silt-clay. Muddy sediments were found in a band running in a southeast to northwest direction from Sandy Hook Bay to Staten Island. Fine-grained sediments were also characteristic of the inner portion of Raritan Bay and borrow pits on the East and West Bank.

3) A total of 521072 animals representing 213 distinct taxa were obtained from the biological samples. There were two particularly abundant species, the amphipod Ampelisca abdita and the blue mussel Mytilus edulis. Ampelisca abdita represented 55.8% and Mytilus edulis 18.6% of the total number of animals collected. Other abundant species included the polychaetes Asabellides oculata and Heteromastus filiformis, the soft shell clam Mya arenaria, the slipper shell Crepidula fornicate, and the amphipods Corophium tuberculatum and Elasmopus levis.

4) Benthic abundance averaged 5714 animals per m^2 and species richness averaged 14.9 species per 0.1 m^2 .

5) Average abundance was high and exceeded comparable values found in many local nearshore environments. Abundance and species richness were on the average substantially higher than that found for the 1973 regional survey conducted by McGrath. These observations, combined with the fact that 213 separate taxa were identified, suggest that the Lower Bay had a rich and diverse benthic fauna during 1986-87.

6) This data set was used in the place of older, less complete data sets in a procedure to select potential sites for large containment islands in the Lower Bay (Figure 1B).

Table 2. Species List	
Porifera	Capitellidae
Unidentified sp.	<i>Capitella capitata</i>
Clionidae	<i>Heteromastus filiformis</i>
<i>Cliona</i> sp.	Chaetopteridae
Cnidaria	<i>Spiochaetoperus oculatus</i>
Anthozoa	Cirratulidae
Unidentified anemone	<i>Cirratulus grandis</i>
Actiniidae	<i>Dodecacera corallii</i>
<i>Tealia felina</i> (tent.)	<i>Tharyx acutus</i>
Ceriantharidae	Flabelligeridae
<i>Ceriantheopsis americanus</i>	<i>Pherusa affinis</i>
Metridiidae	Glyceridae
<i>Metridium senile</i> (tent.)	<i>Glycera americana</i>
Hydrozoa	<i>Glycera capitata</i>
Unidenified hydroid	<i>Glycera dibranchiata</i>
Campanulariidae	Goniadidae
<i>Campanularia flexuosa</i> (tent.)	<i>Goniadella gracilis</i>
Sertulariidae	Hesionidae
<i>Abietinaria abietina</i> (tent.)	<i>Microphthalmus aberrans</i>
Hydractiniidae	<i>Podarke obscura</i>
<i>Hydractinia echinata</i>	Lumbrinereidae
<i>Stylactis hooperi</i>	<i>Lumbrineris acuta</i>
Tubulariidae	<i>Lumbrineris fragilis</i>
<i>Hybocodon prolifer</i>	<i>Lumbrineris impatiens</i>
Platyhelminthes	<i>Lumbrineris tenuis</i>
Unidentified flatworm	Maldanidae
Rhynchocoela	<i>Maldanopsis elongata</i>
Unidentified nemertean	Magelonidae
Aschelminthes	<i>Magelona rosea</i>
Unidentified nematoda	Nephtyidae
Ectoprocta	<i>Nephtys bucera</i>
Unidentified ectoproct	<i>Nephtys incisa</i>
Alcyoniidae	<i>Nephtys picta</i>
<i>Alcyonidium</i> sp.	Nereidae
Calloporidae	<i>Nereis arenaceodonta</i>
<i>Callopora</i> sp.	<i>Nereis succinea</i>
Cheiloporinidae	Onuphidae
<i>Cryptosula</i> sp.	<i>Diopatra cuprea</i>
Electridae	Opheliidae
<i>Electra</i> sp.	<i>Ophelia bicornis</i>
Membraniporidae	<i>Travisia carnea</i>
<i>Conopeum</i> sp.	Orbiniidae
Schizoporellidae	<i>Haploscleroplos fragilis</i>
<i>Schizoporella</i> sp.	<i>Haploscleroplos robustus</i>
Walkeriidae	<i>Orbinia ornata</i>
<i>Aeverrillia</i> sp.	<i>Orbiniidae</i> sp.
Phoronida	Paraonidae
<i>Phoronis architecta</i>	<i>Aricidea catherinae</i>
Annelida	Pectinariidae
Oligochaeta	<i>Pectinaria gouldii</i>
Unidentified sp.	Phyllodocidae
Polychaeta	<i>Eteone heteropoda</i>
Ampharetidae	<i>Eteone lactea</i>
<i>Asabellides oculata</i>	<i>Eumida sanguinea</i>
Arabellidae	<i>Paranaitis speciosa</i>
<i>Drilonereis longa</i>	<i>Phyllodoce arenae</i>

Table 2. Species List (continued)

Polynoidae	
<i>Harmothoe extenuata</i>	
<i>Harmothoe imbricata</i>	
<i>Lepidonotus squamatus</i>	
Sabellidae	
<i>Sabellaria vulgaris</i>	
Sabellidae	
<i>Sabellid sp.</i>	
Potamilla neglecta	
Potamilla reniformis	
<i>Sabella microphthalma</i>	
Serpulidae	
<i>Hydroides dianthus</i>	
Sigalionidae	
<i>Sigalion arenicola</i>	
<i>Sthenelais boa</i>	
<i>Sthenelais limicola</i>	
Spionidae	
<i>Laonice cirrata</i>	
<i>Polydora ligni</i>	
<i>Scolelepis squamata</i>	
<i>Spiophanes bombyx</i>	
<i>Spio setosa</i>	
<i>Streblospio benedicti</i>	
Syllidae	
<i>Autolytus cornutus</i>	
<i>Autolytus prolifer</i>	
<i>Autolytus sp.</i>	
<i>Brania wellfleetensis</i>	
<i>Exogone hebes</i>	
<i>Exogone dispar</i>	
<i>Syllis gracilis</i>	
Terebellidae	
<i>Amphitrite ornata</i>	
<i>Amphitrite sp.</i>	
<i>Polycirrus eximius</i>	
Mollusca	
Gastropoda	
Unidentified nudibrach	
Corambidae	
<i>Corambella sp.</i>	
Acteonidae	
<i>Acteon punctostriatus</i>	
Calyptaeidae	
<i>Crepidula fornicata</i>	
<i>Crepidula plana</i>	
Columbellidae	
<i>Mitrella lunata</i>	
Muricidae	
<i>Eupleura caudata</i>	
<i>Urosalpinx cinereus</i>	
Nassariidae	
<i>Ilyanassa obsoleta</i>	
<i>Nassarius trivittata</i>	
Naticidae	
<i>Lunatia heros</i>	
<i>Lunatia triseriata</i>	
Onchidoridae	
<i>Onchidoris aspera</i>	
Pryamidellidae	
<i>Odostomia producta</i>	
Retusidae	
<i>Retusa obtusa</i>	
Melongenidae	
<i>Busycon canaliculatum</i> -	
Bivalvia	
Arcidae	
<i>Anadara transversa</i>	
Anomiidae	
<i>Anomia simplex</i>	
Cardiidae	
<i>Cerastoderma pinnulatum</i>	
Lyonsiidae	
<i>Lyonsia hyalina</i>	
Mactridae	
<i>Mulinia lateralis</i>	
<i>Spisula solidissima</i>	
Myidae	
<i>Mya arenaria</i>	
Mytilidae	
<i>Mytilus edulis</i>	
<i>Modiolus demissus</i>	
Nuculanidae	
<i>Yoldia limatula</i>	
<i>Yoldia sapotilla</i>	
Nuculidae	
<i>Nucula proxima</i>	
Ostreidae	
<i>Crassostrea virginica</i>	
Pandoridae	
<i>Pandora gouldiana</i>	
Petricolidae	
<i>Petricola pholadiformis</i>	
Solenidae	
<i>Ensis directus</i>	
<i>Siliqua costata</i>	
<i>Solen viridis</i>	
Tellinidae	
<i>Macoma balthica</i>	
<i>Tellina agilis</i>	
Veneridae	
<i>Gemma gemma</i>	
<i>Mercenaria mercenaria</i>	
<i>Pitar morrhuanus</i>	
Arthropoda	
Amphipoda	
Ampeliscidae	
<i>Ampelisca abdita</i>	
<i>Ampelisca vadorum</i>	

Table 2. Species List (continued)

Aoridae	Cirripedia
<i>Microdeutopus gryllotalpa</i>	<i>Balanidae</i>
<i>Unciola dissimilis</i>	<i>Balanus amphitrite</i>
<i>Unciola irrorata</i>	<i>Balanus balanus</i>
<i>Unciola serrata</i>	<i>Balanus eburneus</i>
<i>Unciola sp.</i>	<i>Balanus improvisus</i>
Calliopidae	Mysidacea
<i>Calliopius laeviusculus</i>	<i>Mysidae</i>
Caprellidae	<i>Heteromysis formosa</i>
<i>Unidentified caprellidae</i>	<i>Mysid sp.</i>
Corophiidae	<i>Neomysis americana</i>
<i>Cerupus tubularis</i>	Cumacea
<i>Corophium tuberculatum</i>	<i>Diastylidae</i>
<i>Erichthonius brasiliensis</i>	<i>Unidentified cumacean</i>
Gammaridae	<i>Diastylis polita</i>
<i>Gammarus lawrencianus</i>	<i>Oxyurostylis smithi</i>
<i>Gammarus mucronatus</i>	Decapoda
Haustoriidae	<i>Decapod larva</i>
<i>Acanthohaustorius intermedius</i>	<i>Caridea post larvae</i>
<i>Acanthohaustorius millsi</i>	<i>Brachyurea larva</i>
<i>Acanthohaustorius similis</i>	Cancridae
<i>Acanthohaustorius sp.</i>	<i>Cancer irroratus</i>
Bathyporeia parkeri	Crangonidae
Parahaustorius attenuatus	<i>Crangon septemspinosa</i>
Parahaustorius holmesi	Majidae
Parahaustorius longimerus	<i>Libinia emarginata</i>
Protohaustorius deichmannae	Paguridae
Protohaustorius wigleyi	<i>Pagurus longicarpus</i>
Lysianassidae	Palaemonidae
<i>Lysianopsis alba</i>	<i>Palaemonetes pugio</i>
Melitidae	Portunidae
<i>Elasmopus levis</i>	<i>Callinectes sapidus</i>
<i>Melita nitida</i>	<i>Ovalipes ocellatus</i>
<i>Melitid sp.</i>	Xanthidae
Oedicerotidae	<i>Neopanope texana</i>
<i>Monoculodes edwardsi</i>	<i>Panopeus herbstii</i>
<i>Synchelidium americanum</i>	Isopoda
Phoxocephalidae	Idoteidae
<i>Paraphoxus spinosus</i>	<i>Edotea triloba</i>
<i>Phoxocephalus holbolli</i>	<i>Idotea balthica</i>
<i>Harpinia propinqua</i>	Anthuridae
<i>Rhepoxynius epistomus</i>	<i>Cyathura polita</i>
Stenothoidae	Echinodermata
<i>Parametopella cypris</i>	Asteriidae
<i>Stenothoe minuta</i>	<i>Asterias forbesii</i>
Merostomata	Echinasteridae
Limulidae	<i>Henricia sp.</i>
<i>Limulus polyphemus</i>	Echinarachnidae
Ostrocoda	<i>Echinarachnius parma</i>
<i>Unidentified ostrocoda</i>	Arbaciidae
Copepoda	<i>Arbacia punctulata</i>
<i>Unidentified copepod</i>	Synaptidae
<i>Labidocra aestiva</i>	<i>Leptosynapta inhaerens</i>
Chordata	Molgulidae
	<i>Unidentified tunicate</i>
	<i>Molgula manhattensis</i>

Table 2. Species List (continued)

Vertebrata

Lepophidium cervinum (cusk eel)
Pholis gunnellus (rock eel)
Syngnathus fuscus (pipefish)
Pseudopleuronectes americanus
Ammodytes sp.
Blenny-like larval fish
Pronotus evolans (sea robin)
Myoxocephalus aeneus (sculpin)

Table 4. Abundances of Benthic Invertebrates Compared to Some Local Nearshore Environments

	Average Abundance (number/m ²)	Comments	Reference
Current Study	5714		
Newark Bay	1670	Spring and Summer 1985	Cerrato (1986a)
Newark Bay	273	Fall 1984 - Shoal off Port Newark Terminal	Cerrato and Bokuniewicz (1986)
Raritan Bay	795	Fall 1984 - Shoal off South Amboy	"
Flushing Bay	590	Fall 1984	"
Bowery Bay	127	Fall 1984	"
Moriches Bay	5402	Spring 1969 - Summer 1970	O'Connor (1972)
Moriches Bay	14398	Seasonal 1981-82	Cerrato (1986b)
New York Harbor			
West Bank	536	Seasonal 1980-83 - Borrow Pits and Several Control Sites	Cerrato and Scheier (1984)
Old Orchard Shoal	400	Seasonal 1979-80	Gandarillas and Brinkhuis (1981)
Romer Shoal	400	Seasonal 1979-80	"
East Bank	250	Seasonal 1979-80	"
East Bank	16205	0.5 mm Sieve - Southwest of Rockaway Point	Woodward and Clyde (1975a,b)
Lower Bay	660	Winter 1973 - Regional Study	McGrath (1974) revised by Steimle and Caracciolo-Ward (in review)
Lower Bay	766	West Bank, Old Orchard Shoal, and Nearby Areas	Walford (1971)
South Shore of Long Island			
South Shore of Long Island	1630	Spring, Summer, and Fall 1981	Cerrato (1983)
South Shore of Long Island	1521	Monthly during 1966-67	Steimle and Stone (1973)
Southern New England	2429	0 to 24 meters	Wigley and Theroux (1981)
New York Bight	2430	0 to 24 meters	"
Chesapeake Bight	1742	0 to 24 meters	"

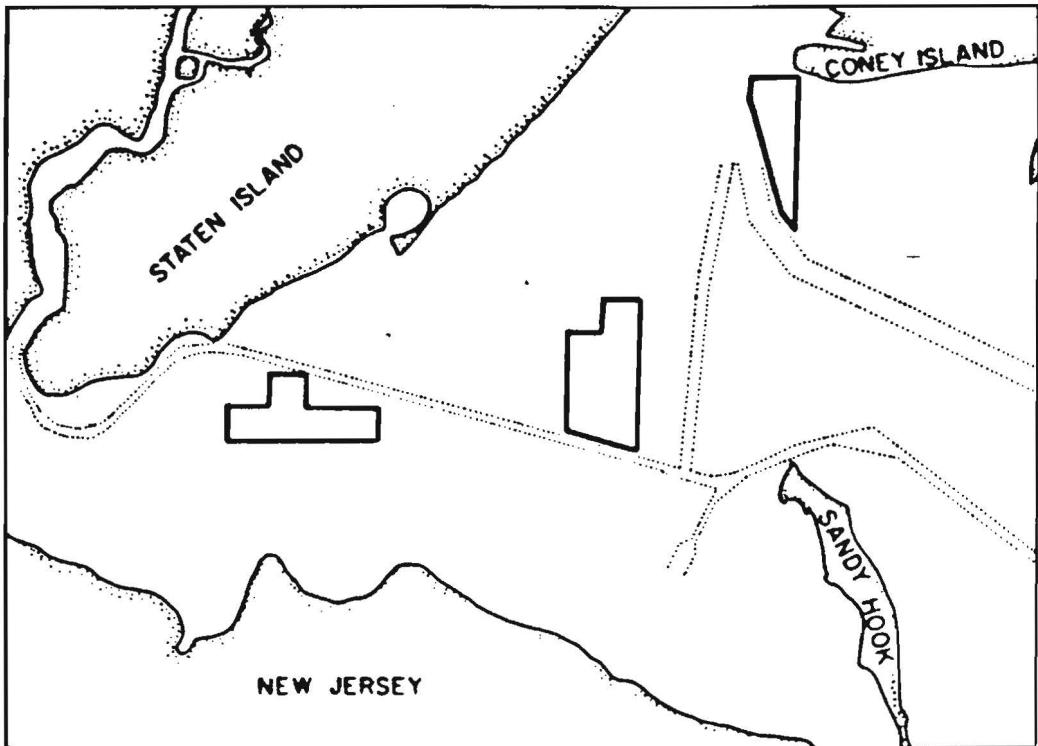

Figure 1A. Potential containment area sites based on data available in 1985 on biological resources and populations (Bokuniewicz and Cerrato, 1985).

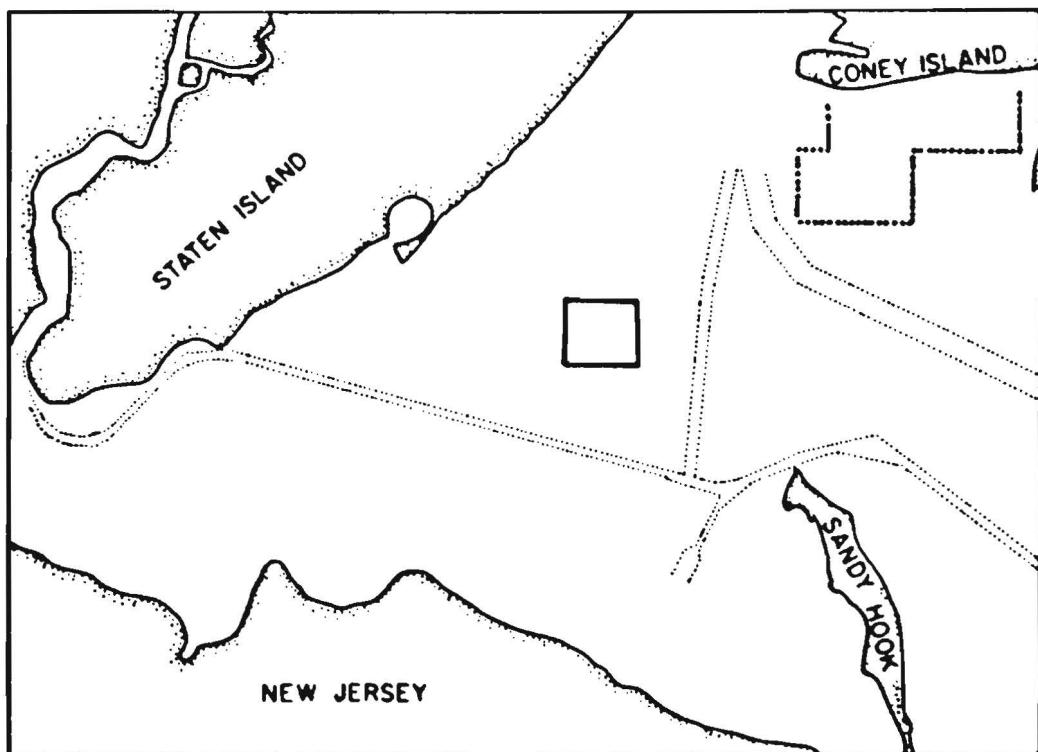

Figure 1B. Potential containment area site (solid line) based on data available in 1988 on biological resources and populations. The area bordered by the dotted line is another low use area but one in shallower water (Cerrato, et al., 1988).
