The Benthic and Epibenthic Fauna
in the Nearshore Atlantic Ocean Waters
Off Northern New Jersey:
Sea Bright to Ocean Township
Biological Monitoring Program
June 1989 Sampling

Robert M. Cerrato
and
Mark H. Wiggins

August 1990

Sponsored by the
Environmental Analysis Branch
New York District
US Army Corps of Engineers

INTRODUCTION

This report describes the results of a June 1989 benthic and epibenthic survey of portions of the nearshore Atlantic Ocean waters off northern New Jersey. Sampling was carried out by the Environmental Analysis Branch of the New York District, Army Corps of Engineers. The goal of this study was to provide baseline information on the distribution and abundance of the benthic and epibenthic organisms at a potential borrow area and a reference site.

METHODS

1. Sampling Procedures

Samples for this study were collected from 5-13 June 1989.

Quantitative benthic samples were obtained using a 0.1 square meter Smith-McIntyre grab. A random sample consisting of sixteen replicate grabs was taken at each of the two locations. Grab samples were wet-sieved onboard immediately after collection. Sieves consisted of 0.5 mm mesh screening. After washing, all material retained on the screen (e.g., animals, detritus, sand, gravel, shell fragments, etc.) was transferred to labeled sample jars. Samples were preserved in 10% buffered formalin and stained with rose bengal.

Qualitative epifaunal samples were collected using a 1.5 m long epibenthic sled. The sled was identical in design but somewhat smaller than the device described by Hessler and Sanders (1966). The mouth of the sled used in this study was 50 cm wide by about 25 cm high. The collecting net was constructed of 6.3 mm mesh stretch nylon. A random sample of four replicate sled tows was taken at each location.

2. Laboratory Procedures

In the laboratory, grab samples were rewashed using a 0.5 mm sieve, transferred to 70% ethyl alcohol, and logged to verify receipt of the sample. Samples were partitioned into five size-fractions by wet-sieving through 6.35, 3.35, 2.0, 1.0, and 0.5 mm mesh screens. Each size-fraction was then analyzed using a two stage process. In the first stage, animals were picked from the sediments, detritus, etc. under an illuminated magnifier (6.3, 3.35, and 2.0 mm fractions) or dissecting microscope (1.0 and 0.5 mm fractions) and sorted to major taxonomic categories. In the second stage, individual organisms were identified to species level whenever possible, and the total for each taxa enumerated. Each taxonomic category was wet-weighed to the nearest 0.001 g. All data were initially entered on log sheets and later transferred to a computer.

Epibenthic samples were rewashed in the laboratory using a 6.35 mm sieve, transferred to 70% ethyl alcohol, and logged to verify receipt of the sample. Samples were then analyzed using a

two stage process. In the first stage, animals were picked from the sediments, detritus, etc. under an illuminated magnifier and sorted to major taxonomic categories. In the second stage, individual organisms were identified to species level whenever possible, and the total for each taxa enumerated. All data were initially entered on log sheets and later transferred to a computer.

RESULTS

A total of 32 Smith-McIntyre grabs and 8 epibenthic sled tow samples were obtained during the June 1989 cruise. The results are listed in tabular form in the remainder of this report. For the Smith-McIntyre grab samples, the lower case letter in the sample identification code indicates the sieve size-fraction. The following scheme was used:

Code	Sieve Size
a	6.35 mm
b	3.35 mm
c	2.00 mm
d	1.00 mm
e	0.50 mm

Grab samples B1-B16, located within the potential borrow area, yielded a total of 75 taxa. Abundances averaged 5,001 individuals per m^2 . Average wet-weight biomass was 17.42 grams per m^2 .

Grab samples B17-B32 were located within the reference area. A total of 86 taxa were collected in these samples. Abundances averaged 18,068 individuals per m^2 , and the average wet-weight biomass was 62.06 grams per m^2 .

Epibenthic sled tow samples E1-E4 and E5-E8 were located within the potential borrow area and the reference area, respectively. The taxa recovered from these two localities were quite similar.
